# Reversal of the Trend in Global Anthropogenic Sulfur Emissions

## ABSTRACT

Global anthropogenic sulfur emissions increased until the late 1980s. Existing estimates for 1995 and 2000 show a moderate decline from 1990 to 1995 or relative stability throughout the decade. This paper combines previously published data and new econometric estimates to show a 25% decline over the decade to a level not seen since the early 1960s. The decline is evident in North America, Western and Eastern Europe and in the last few years in East and South Asia. If this new trend is maintained local air pollution problems will be ameliorated but global warming may be somewhat exacerbated.

## ACKNOWLEDGEMENTS

David Streets (Argonne National Laboratory), Allen Lefohn (ASL and Associates), Rachael Clarke (Environment Australia), Ketan Patel (U.S. EPA), and Cutler Cleveland (Boston University) helped me locate the published data. Chunbo Ma and Lining He provided research assistance. Some of the data was acquired with funding provided by the US EPA under RFQ-DC-04-00027: "Economic Development and Radiatively Important Pollution". Two anonymous referees provided very useful comments and suggestions.

## INTRODUCTION

Anthropogenic sulfur emissions play a crucial role in three important environmental problems: local air pollution and smog, acid rain and dry deposition, and global climate change. Emissions increased fairly continuously until the end of the 1980s (Lefohn *et al.*, 1999). Existing global estimates for 1995 and a forecast for 2000 show a moderate decline from 1990 to 1995 (Olivier *et al.*, 2001) or relative stability throughout the decade (Smith *et al.*, 2001). Here I present data, which combine previously published data and new econometric estimates that show a 24% decline over the decade to a level not seen since the early 1960s. The decline is evident in North America, Western and Eastern Europe and in the last few years in East Asia as well. Emissions per capita in developing countries are far lower than historical emissions in the industrialized world and lower than in all industrialized regions but Western Europe today. These results support recent theoretical and empirical research on the environmental Kuznets curve that suggest that emissions are monotonic in income and reductions in emissions are time-related rather than income-related (Stern, 2004, 2005b). If this new trend is maintained, local air pollution problems will be ameliorated but global warming may be somewhat exacerbated.

As sulfate aerosols increase the planetary albedo both directly and indirectly through increasing cloud cover, sulfur emissions are expected to be correlated with lower solar radiation at the surface. The trends established in this paper conform with recent estimates of changes in solar radiation at the surface from ground-based and satellite observations (Pinker *et al.*, 2005; Wielecki *et al.*, 2005; Wild *et al.*, 2005). These studies show global dimming up till 1985, 1990, or 1992 and a general trend to global brightening, with some regional exceptions, since then. My

estimated changes in anthropogenic sulfur emissions could be an explanation of these trends. However, the reduction in radiative forcing that can be conventionally explained by changes in sulfur emissions is an order of magnitude smaller than some of the observations of surface radiation.

ASL and Associates (1997) produced a database of sulfur emissions (documented by Lefohn *et al.*, 1999) for individual countries for the period 1850-1990 which has been used in a number of climate studies. In the following, I refer to this source as “ASL”. These estimates were superior to all previous global inventories (e.g. Hameed and Dignon, 1992; Spiro *et al.*, 1992) in terms of the combination of spatial and temporal resolution and extent, though individual country and regional inventories may be superior in quality. These data show a 60-fold increase in global emissions from 1850 to 1989 - from 1.2Gg S to 72.2 Gg S. There are some brief reversals in trend particularly during the Great Depression, and towards the end of the First and Second World Wars. (see the line marked ASL in Figure 1).

Two global inventories have been constructed for 1995. But, neither inventory provides the same temporal and spatial resolution and extent that ASL provides for years up till 1990. Smith *et al.* (2001) developed estimates of global sulfur emissions for 1980-1995 and a forecast for 2000. But they do not provide data for individual countries, only for regions (gridded data is available for 1990), and estimates are only given for five-year intervals. Olivier and Berdowski (2001) provide country-by-country estimates for 1990 and 1995 for all countries in the World (referred to in the following as “Edgar”). Both these newer estimates are also shown in Figure 1.

This paper develops a global sulfur emissions data set for most countries of the world from 1850 to 2000 by combining existing published sources and new econometric estimates. The time series should be useful in global change research and the results for the 1990s point to a possible major reversal in the trend of emissions that persisted for more than a century and a half up till the 1980s.

Olivier and Berdowski (2001) estimate that emissions declined 8% from 1990 to 1995. Smith *et al.* (2001) estimate a decline of 7% over the same period but forecast that emissions would again increase by 2000 and they see relative stability over the period 1980 to 2000. ASL indicate a decline in the recession of the early 1980s but a continuation of existing growth trends from then till 1990. My estimates show stability over the 1980s and then a precipitous decline and reversal of the 140-year trend in the 1990s.

The following section describes the methods used to derive these estimates and the remaining sections discuss the results, uncertainties in the estimates, and implications.

## **METHODS**

The estimates combine previously published estimates with new econometric estimates for countries and years with either no data or apparently poor quality estimates. The majority of the total emissions inventory is accounted for by existing estimates that are brought together here for the first time.

The different sources and estimates are prioritized according to the expected level of accuracy of the data. Previously published data are of three types: individual country inventories usually developed by the respective governments, regional inventories (data is provided for individual countries but the same methodology is applied to each country and less detailed modelling is usually undertaken), and global inventories (again data is provided for each country in each year but typically the methods are even less detailed). These three types of published data are used in this order of preference. Less preferred regional or global estimates are only used when official statistics or other single country inventories are not available. The most preferred data is at most available for a few decades and the less detailed estimates are used to estimate the growth rate of emissions in each year and extrapolate or interpolate emissions from a benchmark of the presumed higher quality data. When no previously published data are available, I use my own estimates based on two econometric models and simple linear extrapolation or interpolation, which is the crudest method. Appendices I, III, and IV explain in detail the sources of the data or the estimation method used for each country in each year.

### **Previously Published Data**

For Europe, the former Soviet Union, Japan, the US, Canada, Mexico, Australia, New Zealand, and China data for the 1980s and 1990s, and in some cases earlier years, is available from a series of official sources including national governments and international organizations, that collect information in the form of reports from member governments. These sources are described in detail in Appendix I. For East and South Asia, Streets *et al.* (2000) and Carmichael *et al.* (2002) report estimates for 23 countries for 1985-1997 and 2000. Mylona (1996) provides

estimates at five-year intervals from 1880 to 1980 for most countries in Europe. For 1990 and 1995 I use the Olivier and Berdowski (2001) estimates for all countries not covered by the preceding sources. For years from 1850 to the earliest years provided by each of the preceding sources I estimate emissions by using the growth rates implied by the ASL data.

### **Econometric Emissions Frontier Model**

Where no data is available post 1990 or data appears to be particularly poor in the case of some Eastern European countries and for all Sub-Saharan African countries for 1971-89 except South Africa, I use one of three econometric methods. Where sufficient data is available, I estimate an updated version of the econometric emissions frontier model described in Stern (2002). The new version of the model includes an expanded number of explanatory variables and is estimated using a sample of 73 countries for the period 1971-1990 from the updated database described in Appendices I and II. The model estimates sulfur emissions  $S$  in country  $i$  and year  $t$  using the following function of economic outputs  $y$  and inputs  $x$ :

$$S_{it} = \gamma_i A_i \prod_{j=1}^J y_{jit}^{\alpha_j} \left( \sum_k^K \beta_k x_{it} \right) \varepsilon_{it} \quad (1)$$

where the  $\alpha$ 's,  $\beta$ 's,  $\gamma$ 's, and  $A$ 's are regression coefficients to be estimated using a nonlinear panel data estimation and  $\varepsilon$  is a random error term. The outputs are value-added in services, manufacturing, non-manufacturing industry, and agriculture in country  $i$  and year  $t$ . The inputs are the primary energy inputs: coal, refined oil, natural gas, hydroelectric power, nuclear energy and biomass inputs; primary crude oil supply which is equal to oil refined in country; and

primary smelting of copper, lead, zinc, and nickel. The  $\alpha_j$  coefficients sum to zero.  $\gamma_i$  represents a country specific effect that models the relative efficiency of each country compared to the best practice frontier and  $A_t$  a time specific effect that is intended to model technological change. when estimates are extrapolated it is assumed that technology progresses at the average rate of progress in the estimation period. When a period between available estimates is interpolated, the rate of technological change is adjusted to create a perfect interpolation. For example, for the East Asian countries, I use this model to interpolate estimates for 1998 and 1999. The rate of technological progress is set so that emissions in 2000 are predicted correctly given the 1997 base year. For many other countries, I interpolate between the Edgar estimates for 1990 and 1995. The predictions of the model for sixteen OECD countries in the 1990s were compared to the actual published emissions for those countries with the rate of technological change adjusted to match the 1995 observation. A regression of the logarithms of the published estimates on the logarithms of the predictions yields a coefficient of determination of 0.99 and a slope coefficient that is insignificantly different from unity (Stern, 2005a).

The results of the econometric estimation are presented in Table 1. It is important to note that these effects represent partial derivatives. Therefore, the small coefficient on copper smelting, for example, could indicate that the ore types and technologies differ substantially across countries and that this effect is largely picked up in the country effects. Similarly, the refined oil coefficient is negative and reflects a relative effect holding oil-refining (crude oil) constant. Also, all effects are relative to the base case, which is Algeria in 1971. Given these caveats, the overall pattern of results is somewhat expected with large effects from coal use and oil refining indicated by the crude oil variable. The total technological change effect is a 40% decline in emissions,

*ceteris paribus*, from 1971 to 1990. The most emissions efficient country in the sample is Singapore and the least is Zambia, which makes sense. The implied relative efficiencies are very large. Singapore emits 46 times less sulfur, *ceteris paribus*, than Zambia. The Pedroni cointegration statistic is a model diagnostic that rejects the hypothesis that the relation between the non-stationary variables in the model is spurious and purely due to stochastic trending behavior in the variables included in the model.

### **Environmental Kuznets Curve Model**

When insufficient data are available to estimate (1), I use an environmental Kuznets curve model (EKC). An environmental Kuznets curve is a quadratic in logarithms relating emissions or concentrations of a pollutant to national income per capita. Such a model also includes country and time specific effects with the latter representing technological progress in reducing emissions. Stern (2004) provides an extensive discussion of the EKC literature. Sulfur emissions in year  $t$  and country  $i$  are given by:

$$\ln(S/P)_{it} = \gamma_i + A_t + \beta_1 \ln(Y/P)_{it} + \beta_2 (\ln(Y/P)_{it})^2 + \varepsilon_{it} \quad (2)$$

where  $Y/P$  is GDP per capita in 1995 US dollars adjusted for purchasing power parity (PPP dollars).  $S/P$  is sulfur emissions per capita in kilograms of sulfur. The  $\gamma_i$  are country specific constants or effects and the  $A_t$  are time specific constants or effects that represent technological progress in reducing emissions that is common to all countries.  $\varepsilon_{it}$  is a random error term.

The sample includes 82 countries for the period 1971-1990. The results are presented in Table 2. As found by Stern and Common (2001) and Stern (2002), the EKC is monotonic in income within the income range of the sample as the turning point level of income per capita where emissions begin to decline is \$52590 per capita. The effect of a one percent increase in income is a 0.85% increase in emissions at the sample mean. The reduction in emissions due to time effects is more than twice as great as found by Stern and Common (2001) – a 45% total reduction, *ceteris paribus*. The most efficient country is Hong-Kong and the least Zambia, which are not surprising results.

The Hausman statistic ( $p = 0.03$ ) tests whether the null hypothesis that the explanatory variables are not correlated with the time and country effects (see Stern, 2004 for discussion). In the case of rejection, consistent estimation of a fixed effects model is possible, but the results are conditional on the effects present in the sample. The cointegration test statistic (Pedroni, 1997) rejects the null hypothesis of no cointegration, which means that the estimated relation is statistically valid despite the stochastically trending nature of the variables involved (see Stern, 2004).

Emissions are projected using the sample mean rate of technological progress of  $-2.65\%$  per annum. Raw predictions were modified as necessary as described for the emissions frontier model.

## **Growth Rate Method**

In cases where the data to estimate even model (2) are not available, I use the mean growth rate of sulfur emissions in the previous decade in the country in question to estimate the growth in emissions in the 1990s. In other cases where data for some years are available values are interpolated using a simple linear curve. When no data is available for years before 1990 I assume that emissions in the country in question grew at the same rate as total emissions in the country's region, using the eight global regions described in Appendix V.

## **RESULTS**

Figure 1. presents these new estimates at the global level of aggregation.<sup>1</sup> As Mylona's (1996) estimates are lower than ASL's for the countries she considered in the earlier decades of the time series my global estimates are lower than ASL's up till 1930. From 1930 to 1990 my estimates are higher than ASL's estimates due to the inclusion of more sources of emissions, particularly for developing countries. However the gap reduces. In particular, from 1980 to 1989 there is essentially no change in my estimated global emissions while the ASL estimates increase from 65.7 to 72.2 Gg S. The reason for this slowing trend in my estimates is the beginning of widespread sulfur abatement across many developed countries that was not sufficiently picked up in the ASL modelling. After 1989, with the exception of 1991 when 4.7 Gg S was emitted by

---

<sup>1</sup> Detailed country by country and year by year estimates are available from the author's website at <http://www.rpi.edu/~sternd/> or on request. These results supercede earlier estimates described in Stern (2005a).

the Kuwait oil fires (Husain, 1994),<sup>2</sup> the trend reverses sharply downwards. The trend is due to the collapse of the Soviet Union and Eastern European economies, continued increases in abatement in developed countries, the East Asian financial crisis in 1997, and the beginning of significant efforts to reduce sulfur emissions in China and some other developing countries. Figure 2 illustrates the regional trends for the last three decades for eight major world regions. These regions are defined in the Appendix. Emissions in North America and Western Europe decline throughout the period and emissions in Eastern Europe and the former Soviet Union reverse direction in the late 1980s. Asian emissions increase until 1997 when emissions began to decline, particularly in China. Emissions appear to have only rebounded slightly after economies recovered from the 1997 Asian financial crisis. The big increase in Asian emissions in 1997 is entirely due to increased reported emissions for that year in China. Emissions elsewhere increase over time or decrease in the case of Africa as average incomes fell across the continent. Emissions shifted southward and eastward on a global basis. Figure 3 shows the trends for the northern and southern hemisphere. However, an increasing proportion of emissions is in the Southern Hemisphere and so far no reversal of trend is evident in either South America or Oceania. Estimated emissions do, however, fall in South America in 2000 due to a reduction in copper smelting in Chile.

Interestingly, Oceania is now the “dirtiest” region in terms of emissions per capita (Figure 4) an “honour” formerly held by North America. Figure 4 also shows that prior to 1980 Eastern Europe including the former Soviet Union was not the dirtiest region in terms of per capita

---

<sup>2</sup> This quantity was added to the model projection for Kuwait.

emissions, contrary to popular impressions. More spectacularly, the figure shows that per capita emissions in Asia are the World's lowest and yet appear to be beginning to decline.

From 1987 to 2000 global emissions, decline by 25%. Since 1989 global emissions have fallen at an average rate of 2.6% per annum. The percentage decline in the Great Depression from 1929 to 1932 is around 28% in these data, while the post Second World War decline is 21%. However, those declines are not sustained over such long periods. By 1936 emissions were close to their 1929 level and by 1950 emissions were close to those in 1943.

## **UNCERTAINTIES**

This section addresses the issue of the substantial uncertainties present in estimates of this sort. I do not believe that it is possible to systematically estimate the standard error of the estimates given the disparate sources of uncertainty. Instead I first discuss the potential relative uncertainties of the different data sources and then compare alternative estimates for the world and important countries to give an idea of how much difference the different assumptions and errors make. Finally I look at the available post 2000 data to determine if the decline till 2000 is likely to be maintained.

### **Data and Model Uncertainties**

Uncertainties are present in the existing estimates that I have used, in the input data I have used to construct forecasts for those countries I forecast, and in the parameter estimates of my

econometric models. I believe that the input data for the emissions frontier model forecasts have relatively low uncertainty. Data on energy use and commodities production are probably some of the most reliable of economic statistics. Additionally, the shares of different sectors in GDP change slowly. However, the econometric estimates in Table 1 show that the standard errors of the regression parameters are in many cases very large. In addition, the dependent variable in the regression analysis – estimated sulfur emissions - is uncertain and subject to measurement error – which is likely to reduce the efficiency of estimation, though not bias the estimates (Hausman, 2001). For the EKC model, the explanatory variable – GDP per capita in purchasing power parity dollars is much more uncertain, but the growth rates of GDP over a four year time horizon, which is the maximum extrapolation for most countries are much more accurate.

As explained above, I believe that some of the published data I used are more reliable than others. Official estimates for individual countries mostly are based on more detailed models and better data than estimates from regional and global assessments. Additionally, one might believe estimates for more recent years to be more accurate than for earlier years. However, the introduction of sulfur abatement technologies has introduced a new uncertainty to estimates for recent years. Several authors note that they make limited allowance for sulfur-retention (e.g. Mylona, 1996; Lefohn *et al.*, 1999). Mylona (1996) estimates that true emissions in each country may differ from estimated emissions by  $\pm 30-45\%$  due to uncertainty concerning the sulfur content of fossil fuels. If errors in different countries are not correlated with each other then they may cancel out at the global level, leading to the global estimates being more accurate than those for most individual countries. Smith *et al.* (2001) state that the estimated uncertainty of their global estimate is  $\pm 8\%$ .

## Comparing Different Estimates

Figure 1 compares estimated global emissions for the present study, three other recent global assessments, and the earlier estimates of Dignon and Hameed (1989) and Hameed and Dignon (1992). The studies indicate similar levels of sulfur emissions in the 1980s and 1990s with Olivier and Berdowski estimating the highest level. They include more sources of emissions than the other two estimates. My estimates use individual country estimates that account for much more sulfur abatement in developed countries than the other global assessments include. The different assumptions do not, however, result in extremely different estimates of the level of global sulfur emissions in 1990. Both Smith *et al.* and Olivier and Berdowski estimate that emissions declined between 1990 and 1995. Though, their estimated decline is not as radical as mine, the direction of change is established by all three estimates. Smith *et al.*'s prediction of an increase in emissions from 1995 to 2000 is a forecast and is not based on observations. Smith *et al.*'s estimates for the 1980s and 1990s are very close to my own. I have discussed the differences between my estimates and ASL's above. Dignon and Hameed's estimates are very close to mine in the period before the Second World War, after which they are closer to the ASL estimates. However, the overall picture, is one in which different estimates do not provide very different pictures of global emissions.

Table 3 presents estimates of emissions for the top 20 emitters and Japan in 1990, which according to my estimates contributed 56 Tg S of the total 70 Tg S emitted in that year. According to Edgar the total emissions for this group was 63 Tg S, while according to ASL emissions were 60 Tg S. Taking the lowest estimate for each country, the group would have

emitted 50 Tg S while taking the highest figure for each country results in a total of 69 Tg S. Edgar estimates, therefore, are not always the highest and my estimates are not always the lowest. The biggest percentage variation across estimates is for Japan. Streets *et al.*'s estimate concurs with the official estimate that I use, as does that of Smith *et al.* It is widely accepted that Japan sharply cut emissions in the early 1970s (Smith *et al.*, 2001; Stern, 2005b). In absolute terms though, China and the former Soviet Union have the widest range of emissions estimates. For the former Soviet Union, ASL's estimate is the (low) outlier. The other estimates are close to each other. For China, the official estimate that I use is the lowest, while ASL's estimate is highest. Smith *et al.*'s estimate for China appears to be close to the Edgar estimate. Streets *et al.* come closest to the official figure and are the most aware of the policy, economic, and technological developments in China that are leading to reduced emissions growth. All but one of the other estimates for China reported by Streets *et al.* are lower than their own estimate. Therefore, I contend that even if the official estimate is exaggeratedly low, emissions from China are still probably in the lower part of the range and the error contributed to the global emissions estimate is of the order of 2%.

### **Post-2000 Trends**

How sure can we be that the trend of declining emissions till 2000 will be maintained beyond that year? Some rebound would seem likely in the current business cycle, especially as the downtrend in the 1990s was strongly affected by the collapse of the Soviet Bloc economies. Table 4 reports the available post-2000 data, which are available for the US, and Mexico through 2002 and for China through 2003. Many European countries and Canada have data for 2001.

Though the countries with post-2000 data include the two largest emitters they had less than half the total emissions in 2000. In the three named countries, emissions decline through 2002. They also decline in 2001 in the group with just 2001 data. This year was a recession in many countries. According to SEPA data, emissions then rebounded by more than 1 Tg S in China in 2003. We can conclude that global emissions likely declined through 2002 but that in 2003 and following years emissions could be rebounding moderately.

## **DISCUSSION**

This study has revealed that changes in the pattern of global sulfur emissions have been more dramatic than previously believed (Smith *et al.*, 2001). These results are supported by evidence on the diffusion of pollution abatement technologies to developing countries such as China (Dasgupta *et al.*, 2002; Stern, 2004; Hilton, in press). Success in reducing emissions and concentrations of pollutants such as sulfur dioxide in the developed countries in the 1970s and 1980s helped generate the idea of the environmental Kuznets curve in the early 1990s. This concept supposes that pollution in less developed countries rises as income per capita increases but after a threshold is passed ambient concentrations or per capita emissions are predicted to decline with increasing per capita income. The concept that pollution first rose and then fell with increasing income strengthened pre-existing beliefs that developing countries were “too poor to be green” (Martinez-Alier, 1995) and that the only way to attain a decent environment in most countries is to become rich (Beckerman, 1992). These views have also permeated media and policy debates (Stern, 2004). However, extensive econometric evidence now shows that this model is not statistically robust (e.g. Stern, 2004; Day and Grafton, 2003; Dijkgraaf and

Vollebergh, 1998; Harbaugh *et al.*, 2002; Millimet *et al.*, 2003; Perman and Stern, 2003). Instead emissions of sulfur dioxide, carbon dioxide, and other pollutants appear to increase with rising income but to decrease over time with technological improvements (Stern, 2004).<sup>3</sup> This rate of improvement has been faster in some developed countries but is occurring across a broad range of income levels. Poverty appears to delay but not prevent the adoption of abatement technology (Hilton, in press). The elasticity of emissions with respect to income is likely to fall with rising income but never become negative. This together with faster economic growth rates in some middle-income countries might delay the onset of emissions reductions. The fact that emissions of some pollutants are already falling in East Asia, particularly in China, partly as a result of explicit environmental policies (Dasgupta *et al.*, 2002; Stern, 2004), will eventually have to result in a change in the attitude that only wealthy countries can make environmental improvements or that even wealthy countries cannot afford to make such moves.

A recent set of papers published in *Science* examines a change in trend from declining solar radiation at the Earth's surface ("global dimming") to increasing radiation or "global brightening". From 1960 to 1990 various surface observations indicated a decline of 6-9 Wm<sup>-2</sup> (Wild *et al.*, 2005). Wild *et al.* (2005) find a significant brightening in Europe from 1985 to 2000 from ground based instruments. The turning point was in 1985. Other areas of the world also saw

---

<sup>3</sup> Ambient concentrations of some pollutants may fall with income after a threshold is passed because of the suburbanization and industrial decentralization that accompanies the development process. This decentralization reduces peak and average urban population densities and spreads economic activity and pollution sources more uniformly across space (Stern, 2004).

a brightening or levelling off (China, Australia) with only India showing continued dimming. Surface based BSRN data showed an increase in radiation at the surface of  $6.6 \text{ Wm}^{-2}$  in the period 1992-2001. Earthshine data are similar until 2002. Satellite data examined by Pinker et al. (2005) show an increase of  $0.16 \text{ Wm}^{-2}$  per year from 1983 to 2001 with a minimum in 1990. The CERES satellite data show a  $0.9 \text{ Wm}^{-2}$  brightening over 2000-4 (Wielicki *et al.*, 2005).

Both the date of the turning point and the relative changes in 1960-1990 versus the 1990s in this solar radiation and albedo data closely match the sulfur emission results in this paper. However, the magnitude of the albedo/radiation changes is much greater than conventional estimates of the radiative forcing due to anthropogenic sulfur emissions. Using a standard formula for the direct and indirect effects of sulfur emissions and setting the radiative forcing due to this forcing at a relatively strong  $-2 \text{ Wm}^{-2}$  (Harvey and Kaufmann, 2002) in 1990, we find that the decrease in radiative forcing from 1985 to 2000 should be  $-0.35 \text{ Wm}^{-2}$  with an average annual rate of decline of  $-0.04 \text{ Wm}^{-2}$  from 1991 on. Taking into account the increase in solar irradiance at the top of the atmosphere between 1985 and 1990 (Lean, 2000) results in an estimated decline of  $-0.50 \text{ Wm}^{-2}$ . These maximal potential effects are much less than even the most conservative measurements discussed above. The maximum forcing from the Mount Pinatubo eruption is around  $-3 \text{ Wm}^{-2}$ . This might explain a brightening trend over the 1990s but an increase in stratospheric sulfates could not explain the dimming observed in the previous decades. Overall the high observational values for global dimming and brightening are puzzling as they would swamp the effect of greenhouse gases on the energy budget.

In conclusion, the data presented in this paper, despite some uncertainties, is compatible with existing estimates for earlier periods, can be explained in terms of economic theory and econometric results and seems to match trends in surface solar radiation though it cannot explain the extreme magnitude of those changes.

## Appendix I: Sources of Published Sulfur Data

The countries and sources of the published data are as follows:

**East and South Asia.** Streets *et al.* (2000) report data for 23 countries in East and South Asia: Bangladesh, Bhutan, Brunei, Cambodia, PRC, Hong Kong, India, Indonesia, Japan, North Korea, South Korea, Laos, Malaysia, Mongolia, Myanmar, Nepal, Pakistan, Philippines, Singapore, Sri Lanka, Taiwan, Thailand, and Vietnam. The data are reported in Gg of SO<sub>2</sub>. The period of the data is 1985-97. Carmichael *et al.* (2002) update this data for 2000 and also include data on emissions from ships in Asia. These data are available online at:

[http://www.cgrer.uiowa.edu/people/carmichael/ACCESS/Emission-data\\_main.html](http://www.cgrer.uiowa.edu/people/carmichael/ACCESS/Emission-data_main.html)

Data for emissions from **ships** in Asian waters for 1988, 1990, 1993, 94, and 95 are available in Streets, Guttikunda, and Carmichael (2000). Earlier figures that appear in a chart in Carmichael *et al.* (2002) were supplied by David Streets.

For **Japan** there are also partial OECD data for 1970-1989 and for 1990-2000 Japan has data submitted to the UNFCCC. I interpolate this data using the Streets and ASL data to derive a consistent series.

For **China** for 1995-2003 I use the *State of the Environment Report* and *State Environmental Statistic Report* published by the State Environmental Protection Agency (SEPA) in English or Chinese and available from their website (<http://www.zhb.gov.cn/english/chanel-2/index.php3?chanel=2>). I assumed that Streets *et al.*'s data was correct for 1985 and I used the percentage changes in Streets *et al.*'s data for 1986-1994 with a 3.003% p.a. rate of technological change deducted in order to match up the two series in 1995.

**Europe and the Former Soviet Union.** Data is available from the EMEP website ([www.emep.int](http://www.emep.int)) for 1980-2001 for the following countries: Armenia, Austria, Belarus, Belgium, Bosnia and Hercegovina, Bulgaria, Canada, Croatia, Cyprus, Czech Republic, Denmark, Estonia,

Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Kazakhstan, Latvia, Liechtenstein, Lithuania, Luxembourg, Macedonia, Moldova, Monaco, Netherlands, Norway, Poland, Portugal, Romania, Russian Federation, Slovakia, Slovenia, Spain, Sweden, Switzerland, European Turkey, Ukraine, United Kingdom, Yugoslavia.

Most Western European countries have a complete data set as does the Russian Federation and many other eastern European and former Soviet Union countries. Coverage in others is variable, from a few missing years to only a few years of observations.

Additional data for the 1970s is available from earlier OECD publications for: Denmark, France, Finland, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and the United Kingdom. This data was interpolated where necessary in the same manner as the data for Japan.

For the years 1880-1980 data is available for each fifth year from Mylona (1996) for most countries in Western and Eastern Europe. I interpolated the missing years using the annual growth rates implied by the ASL database adjusted to match the growth over each five year period in the Mylona data.

**Canada.** Canadian data for 1970-2001 are also reported on the site providing the European estimates.

**United States** Data for 1940-2001 are available from US EPA (2000, 2003) and updated to 2002 from the EPA website.

**Australia.** Estimates for 1990-2000 are from the Australian Greenhouse Office (2002).

**New Zealand** Estimates for 1990-2000 are from the UNFCCC website.

**Mexico.** Data for 1985-2002 are from various editions of *Sistema de Cuentas Economicas y Ecologicas de Mexico* published by the Instituto Nacional de Estadística, Geografía e Informática.

**Shipping** Carmichael et al. (2002) provide estimates of emissions from shipping in Asian waters. Estimates for the world as a whole are provided by Smith *et al.* (2001).

**Global** Olivier and Berdowski (2001) provide estimates for all countries for 1990 and 1995. These are used to for 1990 and 1995 for all countries not mentioned above. These data are available online at:

[http://arch.rivm.nl/env/int/coredata/edgar/data32\\_so2.html](http://arch.rivm.nl/env/int/coredata/edgar/data32_so2.html)

and are referred to as Edgar data. For years from 1850 to 1990, data are available from the ASL database described by LeFohn *et al.* (1999). The growth rates implied by this database are used for all observations where the other published estimates described above are not available. For years after 1990 where there is no published data econometric estimates as described in the methods section in this paper were used.

## **Appendix II: Data Sources for Explanatory Variables Used in Econometric Estimates**

### **Energy Use:**

Data are from the International Energy Administration (2002, 2003) for 1986-2000 for non-OECD and for OECD for 1999-2001 (both have select earlier years) and IEA online data. Data were collected for total primary energy supply of crude oil, refined petroleum products, natural gas, coal, hydropower, nuclear power, and biomass fuels. Other energy use categories were considered small enough to ignore. Primary supply of refined petroleum products is equivalent to actual end use oil consumption in a country, while primary supply of crude oil is the quantity of oil refined in a country. Some countries such as the Netherlands carry out extensive oil refining for export, while other countries, such as Germany import significant amounts of refined product.

**GDP and Population:**

I obtained the data from the Penn World Table version 6.1 (Heston *et al.*, 2002). Any gaps were filled from the *World Development Indicators Online*.

**Economic Structure:**

The structure of value added by industry for non-OECD countries was obtained from the *World Development Indicators Online* published by the World Bank (2003). For OECD countries I used data obtained from the *SourceOECD* website.

**Metal Smelting:**

Data on primary production of refined copper, lead, zinc, and nickel for 1980-2000 were received from the United Nations Industrial Development Organization. These data are reported in the *Yearbook of Industrial Statistics*. For copper, lead, and zinc I obtained the same data for 1971-1979 from the hardcopy version. For nickel I obtained data for 1971-1979 from the US Bureau of Mines *Minerals Yearbook*.

**Appendix III: Boundary Changes and Transcontinental Countries**

My general approach is to make borders as comparable as possible to those of the present day. Therefore where countries have merged - for example Germany - I report the figures for the merged country for all years. Where countries have split I report separate figures as far back as possible. This section also reports on methods of interpolation in these countries that were not reported above.

**Czechoslovakia**

From 1980 I report the Czech Republic and Slovakia separately and as a single country before 1980. Estimates for Slovakia for 1981-4 were estimated by interpolating total emissions for Czechoslovakia using the growth rates in the ASL data and subtracting the EMEP data for the Czech Republic.

**Korea**

The ASL database gives separate figures for North and South Korea from 1947.

**Pakistan**

Bangladesh and Pakistan are treated as separate countries starting in 1972 and a single country before that date. Pakistan is included in India for years before 1948.

**Turkey**

Emissions estimates for Turkey as a whole for 1990 and 1995 are provided by Edgar. I estimate emissions for 1991-2000 for Turkey as a whole using the emissions frontier method fine tuned to fit the 1995 Edgar estimates. EMEP data are available for European Turkish emissions for 1980-2000. I extrapolate estimates for 1880-1989 for the whole of Turkey using ASL estimates. Before 1980 estimates for European Turkey are available from Mylona (1996). I interpolate these five yearly figures using the ASL data. Estimates for Asian Turkey are found by subtracting the estimates for European Turkey from those for the whole of Turkey.

**USSR**

For 1990 and 1995 I use the Edgar estimates for those republics/countries without EMEP estimates (Tajikistan, Turkmenistan, Kazakhstan, Azerbaijan, Uzbekistan) and interpolate using the frontier and EKC methods. EMEP data for Russia only cover European Russia. To estimate Asian Russia or Siberia in 1990 and 1995 I subtract the EMEP estimate for Russia from the Edgar estimate for Russia. Total Russian emissions are then interpolated using the EKC and frontier methods. The Edgar estimate for Russia looks very plausible – using the frontier method it would imply that Russia has a similar emissions efficiency to other middle income countries and some less emissions efficient high income countries. Data are reported for the USSR and for constituent republics where available. Estimated emissions for the Soviet Union in 1990 are 23% greater than the ASL estimate. As ASL figures cover the entire USSR, while Mylona only covers the European USSR since the revolution I use the growth rates in the ASL data for years till 1990.

**Vietnam, Germany, and Yemen**

Are each reported as a single country in all years.

**Yugoslavia**

Estimates from 1980 on are given for the separate former Yugoslav republics based on EMEP data and until 1980 for Yugoslavia based on Mylona (1996) and ASL. I interpolate values for Croatia for 1981-89 and for Bosnia and Macedonia for 1980-89 as a constant proportion of Yugoslavia's total EMEP emissions solved iteratively. In the 1990s for Bosnia-Herzegovina I use the Edgar estimate for 1995 and the EMEP value for 2000 and interpolate the other values in the missing years based on the rate of change in the former Yugoslavia as a whole. For Macedonia I use Edgar estimates for 1990 and 1995 and EMEP for 1997 and 2000 and the same method of interpolation. I report estimates for all these countries separately from 1980 on. Emissions for Serbia for 1851 to 1912 are attributed to Yugoslavia.

**Others**

I added Cape of Good Hope to the ASL estimates for South Africa between 1926 and 1935. French Equatorial Africa is attributed to Gabon during 1950-57. French-Indo China refers to Laos. Emissions for French West Africa are attributed to Senegal. Estimates for the Leeward Islands are attributed to Antigua and Barbuda. Rhodesia-Nyasaland are split between Zimbabwe and Malawi from 1950 to 1963 (mostly attributed to Zimbabwe, but allowing for exponential growth in emissions in this period in Malawi). The various states of Malaysia, which appear separately in the ASL database, are reported as a single country. Japan includes the Ryuku Islands when these are listed separately by ASL. Newfoundland data are included in Canada when they are listed separately by ASL. Rwanda and Burundi are reported as separate countries. Hungarian Kingdom data in Mylona was attributed to Hungary.

**Shipping**

Data for shipping in Asian waters were subtracted from the estimates of Smith *et al.* (2001) for global shipping to derive an estimate for shipping in the rest of the World.

## Appendix IV: Methods Used to Estimate Emissions

In this section I note which of the three methods was used to estimate emissions in each country in each year. When not otherwise specified, the data for that country and those years is from the published sources.

### *i. Emissions Frontier Method*

1971-89, 1991-94, and 1996-2000 Benin, Cameroun, Congo, Cote d'Ivoire, Gabon, Ghana, Kenya, Mozambique, Nigeria, Senegal, Tanzania, Zambia, Zimbabwe

1971-76, 1981-89, 1991-94, 1997-2000 Togo

1971-89, 1991-2000 Zaire

1975-76, 1991-94, and 1996-2000 UAE

1981-89, 1991-94, and 1996-2000 Ethiopia

1985-89, 1991-94, and 1996-2000 Angola

1991-93 and 1996-2000 Jamaica

1991-93, 1995-97, 1999-2000 Uruguay

1991-94 and 1996-98 Nicaragua

1991-95 Bahrain

1991-94 and 1996-2000 Albania, Algeria, Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Dominican Republic, Ecuador, Egypt, El Salvador, Guatemala, Honduras, Iran, Jordan, Kuwait, Mexico, Morocco, Namibia, Panama, Paraguay, Peru, Saudi Arabia, South Africa, Syria, Trinidad and Tobago, Tunisia, Turkey, Venezuela, Yemen

1992-1993 and 1995-2000 Uzbekistan

1992-2000 Tajikistan

1992-94 and 1996-2000 Azerbaijan

1996-2000 Cuba, Kazakhstan, Lebanon, Macedonia, Siberia

1998-99 Bangladesh, China, Hong Kong, India, Indonesia, Malaysia, Myanmar, Nepal, Pakistan, Philippines, Singapore, South Korea, Sri Lanka, Taiwan, Thailand, Vietnam

### *ii. EKC Method*

1958-1989, 1991-94, and 1996-2000 Guyana

1960-64 Togo  
 1960-89, 1991-94, and 1996-2000 Rwanda  
 1961-89, 1991-94, and 1996-2000 Cape Verde  
 1969-84 Angola  
 1971-80 Ethiopia  
 1971-89 Namibia  
 1971-89, 1991-94, and 1996-2000 Botswana, Madagascar, Malawi, Mauritania, Mauritius,  
 Niger, Sierra Leone, Swaziland  
 1972-89, 1991-94, and 1996-2000 Haiti  
 1975-79, 1991-94, and 1996-2000 Malta, Sudan  
 1977-89, 1991-94, and 1996-2000 Antigua and Barbuda  
 1978-89, 1991-94, 1996-2000 Uganda  
 1982-88 Liberia  
 1985-89 and 1991 Tajikistan  
 1986-89, 1991-94, and 1996-2000 The Bahamas  
 1987-89, 1991-94, and 1996-2000 Turkmenistan  
 1987-89, 1991-94, and 1996-2000 Oman  
 1991 Uzbekistan  
 1991-93 Cuba, Lebanon  
 1991-94 Kazakhstan, Macedonia, Siberia  
 1991-94 and 1996-2000 Israel  
 1991-94 and 1996-2000 Barbados, Fiji, Malta, Papua New Guinea, Qatar, Surinam  
 1996-2000 Bahrain  
 1998-99 Bhutan, Cambodia, Laos, Mongolia

**iii. Growth Rates Method**

1989, 1991-94 1996-2000 Liberia.  
 1991-1994 Kazakhstan, Tajikistan  
 1991-94 and 1996-2000 Afghanistan, Bermuda, Burkina Faso, Central African Republic, Chad,  
 Djibouti, Eritrea, Faeroe Islands, Gibraltar, Greenland, Guam, Guinea, Guinea-Bissau, Iraq,

Libya, Macao, Mali, Martinique, Netherlands Antilles and Aruba, New Caledonia, Puerto Rico, Reunion, Saint Pierre and Miquelon, Somalia, US Virgin Islands

1996-99 Bosnia and Herzegovina

1998-99 Brunei, North Korea

## **Appendix V: Regions**

The regions include the following countries:

**W. Europe:** Austria, Belgium, Cyprus, Denmark, Faeroe Islands, Finland, France, Germany, Gibraltar, Greece, Iceland, Ireland, Italy, Liechtenstein, Luxembourg, Malta, Monaco, Netherlands, Norway, Poland, Portugal, Spain, Sweden, Switzerland, European Turkey, United Kingdom.

**E. Europe and the Former Soviet Union:** Albania, Armenia, Asian USSR, Azerbaijan, Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, Czech Republic, Czechoslovakia, Estonia, European Russia, FYR Macedonia, Georgia, Hungary, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Moldova, Romania, Serbia, Serbia-Montenegro, Siberia, Slovakia, Slovenia, Tajikistan, Turkmenistan, Ukraine, USSR, Uzbekistan, Yugoslavia.

**Middle East and North Africa:** Algeria, Bahrain, Egypt, Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Libya, Morocco, Oman, Qatar, Saudi Arabia, Syria, Tunisia, Asian Turkey, UAE, Yemen.

**Asia:** Afghanistan, Bangladesh, Bhutan, Brunei, Cambodia, China, Hong Kong, India, Indonesia, Japan, Korea, Laos, Macau, Malaysia, Mongolia, Myanmar, Nepal, North Korea, Pakistan, Philippines, Singapore, South Korea, Sri Lanka, Taiwan, Thailand, Vietnam.

**Africa:** Angola, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Cape Verde, Central African Republic, Chad, Congo, Cote d'Ivoire, Djibouti, Eritrea, Ethiopia, Gabon, Ghana, Guinea, Guinea-Bissau, Kenya, Liberia, Madagascar, Malawi, Mali, Mauritania, Mauritius, Mozambique, Namibia, Niger, Nigeria, Reunion, Rwanda, Senegal, Sierra Leone, Somalia, South Africa, Sudan, Swaziland, Tanzania, Togo, Uganda, Zaire, Zambia, Zimbabwe.

**Oceania:** Australia, Fiji, Guam, New Caledonia, New Zealand, Papua New Guinea.

**Anglo America:** Bahamas, Bermuda, Canada, Greenland, Puerto Rico, St Pierre et Miquelon, USA, US Virgin Islands.

**Latin America:** Antigua and Barbuda, Argentina, Barbados, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominican Rep., Ecuador, El Salvador, Guatemala, Guyana, Haiti, Honduras, Jamaica, Martinique, Mexico, Netherlands Antilles and Aruba, Nicaragua, Panama, Paraguay, Peru, Surinam, Trinidad, Uruguay, Venezuela.

**Table 1. Econometric Emissions Frontier Model**

Variable	Coefficient	Standard Error
Agricultural GDP	-0.0504	0.0307
Manufacturing GDP	0.2249	0.0358
Non- manufacturing GDP	0.0310	0.0230
